

(Munkres §24)

Q is  $\mathbb{R}$  connected in the analytic topology?  
why is this tricky?

last time, showed:

$\mathbb{Q}$  as a subspace of  $\mathbb{R}$  is disconnected,  
even though it is dense in  $\mathbb{R}$  (i.e.  $\text{Cl}_{\mathbb{R}}(\mathbb{Q}) = \mathbb{R}$ )

any proof that  $\mathbb{R}$  is connected must use  
some fact about  $\mathbb{R}$  that fails for  $\mathbb{Q}$

Df given a set  $X$  with a total order  $<$   
it has the least upper bound property iff  
every subset of  $X$  bounded above  
has a least upper bound ( = sup )

Ex in an intro analysis course,  
we define  $\mathbb{R}$  from scratch

the defn shows that  $\mathbb{R}$  has the LUBP  
but  $\mathbb{Q}$  does not: e.g.  $\{x \in \mathbb{Q} \mid x^2 < 2\}$  has no LUB

the LUBP is not enough to prove  $\mathbb{R}$  is connected:  
why?

Ex if  $X \subset \mathbb{R}$  finite and  $|X| \geq 2$   
then  $X$  disconnected but has the LUBP

Df a set  $X$  with a total order  $<$  is called  
a linear continuum iff

- 1) it has the LUBP
- 2) for all  $x < y$  in  $X$ , there is  $z$  s.t.  $x < z < y$

thus  $R$  is a linear continuum

Thm  $R$  is connected in the analytic topology

Pf suppose  $U, V$  form a separation of  $R$   
pick  $a$  in  $U$  and  $b$  in  $V$   
WLOG we can assume  $a < b$

let  $A = [a, b] \cap U$  and  $B = [a, b] \cap V$

then  $A, B$  form a separation of  $[a, b]$

in its subspace top

but  $A$  is bounded above by  $b$

so by the LUBP,  $\sup A$  exists and is in  $[a, b]$

remains to show 1)  $\sup A \notin B$

2)  $\sup A \notin A$

1) assume  $\sup A \in B$

then  $\sup A > a$ : else  $A = \emptyset$

but  $B$  is open in  $[a, b]$ , so  $(\sup A - \delta, \sup A] \subset B$   
for some  $\delta > 0$

but then,  $\sup A - \varepsilon$  is a smaller upper bound for  $A$   
whenever  $0 < \varepsilon \leq \delta$

2) assume  $\sup A \in A$

then  $\sup A < b$ : else,  $B = \emptyset$

but  $A$  is open in  $[a, b]$ , so  $[\sup A, \sup A + \delta) \subset A$   
for some  $\delta > 0$

but then  $\sup A + \varepsilon$  is an elt of  $A$  above  $\sup A$   
whenever  $0 < \varepsilon < \delta$   $\square$

Rem thm generalizes to any linear continuum  
in its order topology (we did not define)

for this course, just note:

the proof still works if we replace  $\mathbb{R}$  with

$(a, b), (a, b], [a, b), [a, b]$

$(-\infty, b), (-\infty, b], (a, \infty), [a, \infty)$

Thm (Intermediate Value)

suppose  $X$  connected and  $f : X$  to  $\mathbb{R}$  cts

wrt the analytic top on  $\mathbb{R}$

if  $a, b$  in  $X$  and  $f(a) \leq \alpha \leq f(b)$

then there is some  $c$  in  $X$  s.t.  $f(c) = \alpha$

Lem if  $X$  is connected,  $f : X$  to  $Y$  cts,  
then  $f(X)$  sub  $Y$  is connected

Pf preimage of separation is a separation

Pf of Thm suppose no  $c$  in  $X$  s.t.  $f(c) = \alpha$

then  $f(X)$  has a separation:  $\{f(x) < \alpha \mid x \text{ in } X\},$   
 $\{f(x) > \alpha \mid x \text{ in } X\}$

but  $X$  is connected, so contradiction with lemma

Moral the connectedness of intervals in  $\mathbb{R}$   
is very well-understood

Idea study connectedness in other spaces  
by comparing them to intervals in  $\mathbb{R}$

Df for any  $X$  and  $x, y$  in  $X$   
a path from  $x$  to  $y$  is a cts map  
 $\gamma : [a, b]$  to  $X$  s.t.  $\gamma(a) = x$  and  $\gamma(b) = y$

we say  $X$  is path-connected iff  
there is a path between every pair of pts in  $X$

Rem we require  $a \leq b$   
but otherwise  $a, b$  can be any numbers

Lem if  $X$  is path-connected  
then  $X$  is connected

Pf if  $X = \emptyset$ , then done  
else, can fix  $x$  in  $X$

for all  $y$  in  $X$ , pick a path  $\gamma_y$  from  $x$  to  $y$   
then  $X = \bigcup \gamma_y([0, 1])$   
each  $\gamma_y([0, 1])$  is connected and contains  $x$   
so  $X$  is connected

[famous non-example:]

Ex in analytic  $\mathbb{R}^2$ : consider  
 $S = \{(x, \sin(1/x)) \mid 0 < x \leq 1\}$   
 $A = \{(0, y) \mid -1 \leq y \leq 1\}$   
 $\check{S} = S \cup A = \text{the closure of } S \text{ in } \mathbb{R}^2$

the topologist's sine curve:  $\check{S}$  in its subspace top.

not hard:  $S, A$  are path-connected  
 $\check{S}$  is connected [since  $S$  is] [pf next time]  
claim:  $\check{S}$  is not path-connected

sketch: fix  $a$  in  $A$  and  $s$  in  $S$   
 suppose  $\gamma : [0, 1]$  to  $\check{S}$  a path from  $a$  to  $s$

claim there is a largest  $t_0$  in  $[0, 1]$  s.t.  $\gamma(t_0)$  in  $A$ :  
 $A$  is closed in  $R$ , hence in  $\check{S}$   
 so  $\gamma^{-1}(A)$  is closed in  $[0, 1]$   
 so  $\gamma^{-1}(A)$  is its own closure  
 so it contains its sup

so for all  $t$  in  $(t_0, 1]$ , have  $\gamma(t)$  in  $S$   
 let  $(t_n)_n$  be a decreasing seq converging to  $t_0$   
 for all  $n$ : pick  $0 < x_n < x\text{-coord}(\gamma(t_n))$  s.t.  
 $\sin(1/x_n) = (-1)^n$   
 by IVT:  $x\text{-coord}(\gamma(t_0)) < x_n < x\text{-coord}(\gamma(t_n))$   
 means there is  $t'_n$  in  $[t_0, t_n]$  s.t.  
 $\gamma(t'_n) = x_n$

(Munkres §25)

Lem for any  $X$ , the following are equiv. rel's:

- 1)  $x \sim y$  iff there is a connected subspace of  $X$   
 that contains both  $x$  and  $y$
- 2)  $x \leftrightarrow y$  iff there is a path between  $x$  and  $y$  in  $X$

Pf transitivity for 1): if  $x, y$  in  $A$  &  $y, z$  in  $B$ ,  
 then  $A \cap B \ni y$   
 transitivity for 2): [Munkres 18.3:]

Pasting Lem let  $Y = Y_1 \cup Y_2$   
 $f_i : Y_i$  to  $X$  for  $i = 1, 2$

if  $f_1, f_2$  cts and  $f_1(x) = f_2(x)$  on  $Y_1 \cap Y_2$   
 then  $f : Y$  to  $X$  def by  $f|_{Y_i} = f_i$  is cts

Pf boring

Df the connected components of  $X$  are  
the equiv. classes under  $\sim$   
the path components of  $X$  are  
the equiv. classes under  $\leftrightarrow$

Ex with some work, we can show:

$S$  and  $A$  are the conn. components of  $\check{S}$ ,  
and also, its path components
