- 5 Steinberg Varieties for  $\mathbf{G}$

## 1 Charged Partitions    Fix an integer $l > 0$ .

An integer partition  $\lambda \in \Pi$  is called an  $l$ -core iff it has no hook lengths divisible by  $l$ .

- 1-cores:  $\emptyset$ .
- 2-cores: staircase partitions.
- $l$ -cores for  $l \geq 3$ : complicated.

An analogue of long division for partitions:

$$l\text{-core} \times l\text{-quotient} : \Pi \xrightarrow{\sim} \Pi_{l\text{-cor}} \times \Pi^l.$$

Our starting point is its application to *quantum groups* and *finite reductive groups*.

First, repackage it as a bijection

$$\Upsilon_l : \Pi \times \mathbf{Z} \xrightarrow{\sim} \Pi^l \times \mathbf{Z}^l.$$

Elements of  $\Pi^l \times \mathbf{Z}^l$  are called *charged  $l$ -partitions*.

We'll need  $\mathbf{B} = \{\beta \mid \mathbf{Z}_{<x} \subseteq \beta \subseteq \mathbf{Z}_{<y} \text{ for some } x, y\}$ .

Elements of  $\mathbf{B}^l$  are  *$l$ -abacus configurations*.

*Step 1.*  $\Pi \times \mathbf{Z} \simeq \mathbf{B}$  via

$$|\pi, s\rangle \leftrightarrow \{s + \pi_i - i + 1 \mid i = 1, 2, 3, \dots\}.$$

*Step 2.*  $\vec{v}_l : \mathbf{B} \xrightarrow{\sim} \mathbf{B}^l$  given by

$$v_l^{(r)}(\beta) = \{q \in \mathbf{Z} \mid lq + r \in \beta\} \quad \text{for all } r \bmod l.$$

$$\Upsilon_l(\pi, 0) = |\vec{\pi}, \vec{s}\rangle \iff \begin{cases} \Upsilon_l(l\text{-core}(\pi), 0) = |\vec{\emptyset}, \vec{s}\rangle, \\ l\text{-quotient}(\pi) = \vec{\pi}. \end{cases}$$

Ex Take  $|\pi, s\rangle = |(2, 2, 1), 4\rangle$  and  $l = 3$ .

The charged 3-partition:  $|((\emptyset, \emptyset, (1)), (2, 0, 0))\rangle$ .

We do have  $\Upsilon_3(3\text{-core}(\pi), s) = |\vec{\emptyset}, (2, 0, 0)\rangle$ .

2 Cyclotomic Hecke Algebras Let  $\mathfrak{S}_{N,l} = \mathfrak{S}_N \ltimes \mathbf{Z}_l^N$ .

From partitions to representations:

- $\text{Irr}(\mathfrak{S}_n) \simeq \{\pi \in \Pi \mid \pi \vdash n\}$ .
- $\text{Irr}(\mathfrak{S}_{N,l}) \simeq \{\vec{\pi} \in \Pi^l \mid |\vec{\pi}| \vdash_l N\}$ .

Actually, we'll use the *Ariki-Koike algebra*

$$H_{N,l}(u, \vec{v}) = \frac{\mathbf{C}[u^{\pm 1}, v_1^{\pm 1}, \dots, v_{\ell-1}^{\pm 1}] \mathfrak{B}_{N,l}}{\left\langle \begin{array}{l} (\sigma_i - 1)(\sigma_i + u) \text{ for all } i, \\ (\tau - 1)(\tau - v_1) \cdots (\tau - v_{l-1}) \end{array} \right\rangle},$$

By Tits deformation,  $\text{Irr}(\mathfrak{S}_{N,l}) \simeq \text{Irr}(H_{N,l}(u, \vec{v}))$ .

For general  $m$  and  $\vec{s}$ , nontrivial *decomposition map*

$$K_0(H_{N,l}(u, \vec{v})) \rightarrow K_0(H_{N,l}(\zeta_m, \vec{\zeta}_m^s)).$$

(Ariki) For  $l, m$ , and  $\vec{s} \in \mathbf{Z}^l$ : Description of

$$\mathbf{Q}K_0(H_{N,l}(\zeta_m, \vec{\zeta}_m^s)) \quad \text{for } N \geq 0$$

via a  $U'_v(\widehat{\mathfrak{sl}}_m)_{\mathbf{Q}}$ -module

$$\Lambda_{\vec{s}} := \bigoplus_{\vec{\lambda} \in \Pi^l} \mathbf{Q}(v) |\vec{\lambda}, \vec{s}\rangle$$

called the *Fock space of level  $l$  and charge  $\vec{s}$* .

(Uglov) For  $(\vec{s}, \vec{r}) \in \mathbf{Z}^l \times \mathbf{Z}^m$  such that  $|\vec{s}| = s = |\vec{r}|$ :

Commuting  $U'_v(\widehat{\mathfrak{sl}}_m)_{\mathbf{Q}}$ - and  $U'_v(\widehat{\mathfrak{sl}}_l)_{\mathbf{Q}}$ -actions on

$$\Lambda_{\vec{s}} \stackrel{\Upsilon_l}{=} \Lambda_s \stackrel{\bar{\Upsilon}_m}{=} \Lambda_{\vec{r}}$$

where  $\bar{\Upsilon}_m$  is a modified version of  $\Upsilon_m$ .

(Uglov) Bijections of the form below, matching decomposition numbers on the two sides:

$$\begin{array}{ccc} \mathrm{Irr}(\mathfrak{S}_{N,l})_{\mathbf{b}} & \simeq & \mathrm{Irr}(\mathfrak{S}_{N',m})_{\mathbf{c}} \\ \uparrow & & \uparrow \\ \mathbf{b} \trianglelefteq K_0(H_{N,l}(\zeta_m, \vec{\zeta}_m^s)) & & K_0(H_{N',m}(\zeta_l, \vec{\zeta}_l^r)) \trianglerighteq \mathbf{c} \end{array}$$

(Losev, Rouquier–Shan–Varagnolo–Vasserot, Webster)

$$\mathrm{Rep}_{\mathbf{b}}(H_{N,l}^{\mathrm{rat}}(\vec{\nu}_l)) \simeq \mathrm{Rep}_{\mathbf{c}}(H_{N',m}^{\mathrm{rat}}(\vec{\nu}_m))$$

for *cyclotomic rational DAHAs*  $H_{N,l}^{\mathrm{rat}}, H_{N',m}^{\mathrm{rat}}$ .

- $\zeta_m^s = e^{2\pi i \vec{\nu}_l}$  and  $\zeta_l^r = e^{2\pi i \vec{\nu}_m}$ .
- $\mathrm{Rep}_{\mathbf{b}}, \mathrm{Rep}_{\mathbf{c}}$  lift  $\mathbf{b}, \mathbf{c}$ .

These equivalences are called *level-rank dualities*.

3  $\Phi$ -Harish-Chandra Theories Ting Xue and I propose a generalization to *relative Weyl groups*.

Fix a prime power  $q$ . A reductive group  $\mathbf{G}$  with Frobenius  $F : \mathbf{G} \rightarrow \mathbf{G}$  over  $\bar{\mathbf{F}}_q$  defines a

$$\text{finite reductive group } G = \mathbf{G}^F.$$

Let  $\mathrm{Uch}(G)$  index its *unipotent irreducible characters*.

(Harish–Chandra)  $\mathrm{Uch}(G) = \coprod_{(L,\lambda)} \mathrm{Uch}(G)_{L,\lambda}$ .

- $L \subseteq G$  is an  $F$ -maximally split Levi.
- $\lambda \in \mathrm{Uch}(L)$  is *cuspidal*.
- $\mathrm{Uch}(G)_{L,\lambda} = \{\rho \in \mathrm{Uch}(G) \mid (\rho, \mathrm{Ind}_L^G(\lambda)) \neq 0\}$ .

Relative Weyl groups:  $W_{G,L,\lambda} = C_{N_G(L)/L}(\lambda)$ .

How to introduce  $l, m$ ?

(Broué–Malle–Michel) A Levi  $L$  is  $\Phi_l$ -split iff

$$L = Z_G(T)^\circ \quad \text{for some torus } \mathbf{T} \subseteq \mathbf{G} \text{ such that} \\ |T| \text{ is generically a power of } \Phi_l(q).$$

( $\mathbf{T}$  need not be maximal!)

$\lambda \in \text{Uch}(L)$  is  $\Phi_l$ -cuspidal iff it does not occur in the Lusztig induction  $\mathbf{R}_M^L$  from smaller  $\Phi_l$ -split Levis  $M$ .

$\Phi_l$ -cuspidal pairs and  $\Phi_l$ -Harish-Chandra series:

- $\text{Uch}(G) = \coprod_{\Phi_l\text{-cuspidal } (L, \lambda)} \text{Uch}(G)_{L, \lambda}.$
- Bijections  $\text{Uch}(G)_{L, \lambda} \xrightarrow{\chi_{L, \lambda}} \text{Irr}(W_{G, L, \lambda}).$
- Signs  $\text{Uch}(G)_{L, \lambda} \xrightarrow{\varepsilon_{L, \lambda}} \{\pm 1\} \implies \text{isometries } \varepsilon \chi.$

Ex Take  $G = \text{GL}_n(\mathbf{F}_q)$ , so that  $\text{Uch}(G) \simeq \{\pi \vdash n\}.$

$\Phi_l$ -split Levi $L$	$\text{GL}_{\mathbf{N}}(\mathbf{F}_q) \times (\mathbf{F}_{q^l})^{\frac{n-N}{l}}$
$\Phi_l$ -cuspidal $\lambda \in \text{Uch}(L)$	$l$ -core $\lambda \vdash N$
$\text{Uch}(G)_{L, \lambda}$	$\{\pi \vdash n \mid l\text{-core}(\pi) = \lambda\}$

Above,  $W_{G, L, \lambda} \simeq S_N \ltimes \mathbf{Z}_l^N$ . The map

$$\chi_{L, \lambda} : \text{Uch}(G)_{L, \lambda} \rightarrow \text{Irr}(W_{G, L, \lambda})$$

comes from the  $\Pi^l$  part of  $\Upsilon_l(-, \text{len}(\lambda)).$

$\mathbf{R}_L^G := \text{H}_c^*(Y_L^G)$  for some Deligne–Lusztig variety  $Y_L^G$ .

Conj (BMM)  $\text{End}_G(\text{H}_c^*(Y_L^G)[\lambda]) \simeq H_{N, l}(q^l, q^{\vec{a}(\lambda)}).$

Above,  $\vec{a}(\lambda) = l\vec{a}'(\lambda) + (0, 1, \dots, l-1)$ , where  $\vec{a}'$  is the  $\mathbf{Z}^l$  part of  $\Upsilon_l(\lambda, \text{len}(\lambda)).$

Conj (BMM) For *general*  $G$  and  $\Phi_l$ -cuspidal  $(L, \lambda)$ ,

$$\text{End}_G(H_c^*(Y_L^G)[\lambda]) \simeq H_{W_{G,L,\lambda}}(q)$$

for an *explicit* 1-parameter algebra  $H_{W_{G,L,\lambda}}(x)$ . And the commuting actions induce

$$\chi_{L,\lambda} : \text{Uch}(G)_{L,\lambda} \rightarrow \text{Irr}(H_{W_{G,L,\lambda}}(q)) = \text{Irr}(W_{G,L,\lambda}).$$

(Lusztig) True for  $l = 1$  cases and “Coxeter tori”.

(Digne–Michel–Rouquier) Progress in types  $A, B, D_4$ .

Our generalization of level-rank duality will involve

$$H_{W_{G,L,\lambda}}(\zeta_m) \text{ versus } H_{W_{G,M,\mu}}(\zeta_l),$$

for  $\Phi_l$ -cuspidal  $(L, \lambda)$  and  $\Phi_m$ -cuspidal  $(M, \mu)$ .

Let  $\text{Uch}_{L,\lambda,M,\mu}^G = \text{Uch}(G)_{L,\lambda} \cap \text{Uch}(G)_{M,\mu}$ . Form

$$\text{Irr}(W_{G,L,\lambda}) \xleftarrow{\chi_{L,\lambda}} \text{Uch}_{L,\lambda,M,\mu}^G \xrightarrow{\chi_{M,\mu}} \text{Irr}(W_{G,M,\mu}).$$

Conj (T–Xue)

- 1 The left / right image is a union of preimages of blocks of  $H_{G,L,\lambda}(\zeta_m)$  /  $H_{G,M,\mu}(\zeta_l)$ .
- 2 The maps descend to a bijection

$$\{H_{G,L,\lambda}(\zeta_m)\text{-blocks}\} \simeq \{H_{G,M,\mu}(\zeta_l)\text{-blocks}\}.$$

- 3 For matching blocks, an equivalence of their highest-weight covers (= blocks of rational DAHAs).

Thm (T–Xue) Take  $G = \text{GL}_n$  and  $l, m$  coprime.

Then (1)–(3) hold when  $H_{G,L,\lambda}(x) = H_{N,l}(x^l, x^{\vec{a}(\lambda)})$ . In (1), the images are single blocks.

#### 4 Steinberg Varieties for $\mathbf{G}^F$ (Recall $G = \mathbf{G}^F$ .)

A more explicit version of the BMM conjecture:

$$\begin{aligned} R_L^G(\lambda) &:= \sum_i (-1)^i H_c^i(Y_L^G)[\lambda] \\ &= \sum_{\rho \in \text{Uch}(G)_{L,\lambda}} \rho \otimes \varepsilon_{L,\lambda}(\rho) \chi_{L,\lambda}(\rho)_q \end{aligned}$$

as a virtual  $(G, H_{W_{G,L,\lambda}}(q))$ -bimodule.

Suggests looking at

$$R_L^G(\lambda) \otimes_{\mathbf{C}G} R_M^G(\mu)$$

as a virtual  $(H_{W_{G,L,\lambda}}(q), H_{W_{G,M,\mu}}(q))$ -bimodule.

Let  $\mathcal{B}$  be the flag variety of  $\mathbf{G}$ . For  $w \in W$ , set

$$\mathcal{Y}_w = \{(g, B) \in \mathbf{G} \times \mathcal{B} \mid B \xrightarrow{w} gFB(gF)^{-1}\}.$$

Action  $\mathbf{G} \curvearrowright \mathcal{Y}_w$  via  $x \cdot (g, B) = xgF(x)^{-1}, xBx^{-1}$ .

If  $L$  is a maximal torus of type  $[w]$ , then

$$\mathbf{R}_L^G(1_L) = H_c^*(Y_L^G)[1_L] \simeq H_{c,\mathbf{G}}^*(\mathcal{Y}_w).$$

For  $L, M$  maximal tori of types  $[w], [v]$ , we are led to consider the *generalized Steinberg variety*

$$\mathcal{Y}_w \times_{\mathbf{G}}^L \mathcal{Y}_v.$$

Some (derived) Künneth-type formula should show

$$R_L^G(\lambda) \otimes_{\mathbf{C}G} R_M^G(\mu) = \sum_i (-1)^i H_{c,\mathbf{G}}^i(\mathcal{Y}_w \times_{\mathbf{G}}^L \mathcal{Y}_v).$$

## 5 Steinberg Varieties for $\mathbf{G}$

Earlier, I introduced similar varieties in a totally independent context.

Let  $\mathcal{U} \subseteq \mathbf{G}$  be the *unipotent locus*. Let

$$\mathcal{U}_w = \{(u, B) \in \mathcal{U} \times \mathcal{B} \mid B \xrightarrow{w} uBu^{-1}\}.$$

For example,  $\mathcal{U}_e$  is the (groupy) Springer resolution.

I studied an action of  $\mathbf{H}_W := \mathrm{gr}_*^W \mathrm{H}_{c, \mathbf{G}}^*(\mathcal{U}_e \times_{\mathcal{U}}^L \mathcal{U}_e)$  on

$$\mathrm{gr}_*^W \mathrm{H}_{c, \mathbf{G}}^*(\mathcal{U}_e \times_{\mathcal{U}}^L \mathcal{U}_w).$$

(Actually a braid version motivated by link homology.)

Above,  $\mathbf{H}_W \simeq \mathbf{C}W \ltimes \mathrm{Sym}(X_*(\mathbf{A}))$ , where  $\mathbf{A} \subseteq \mathbf{G}$  is a maximally split maximal torus. ( $W = W_{G, \mathbf{A}, 1}$ .)

Via the  $W$ -action, the  $\mathbf{G}$ -equivariant virtual weight polynomial defines a  $\mathbf{Z}W[x]$ -valued *virtual character*.

**Thm (T)** Suppose that  $w \in W$  is *regular* of order  $m$ .

Then the virtual character of  $\mathcal{U}_e \times_{\mathcal{U}}^L \mathcal{U}_w$  is given by

$$\sum_{\rho \in \mathrm{Uch}(G)_{A, 1, M, 1}} D_m(\rho) [\Delta_{1/m}(\chi_{A, 1}(\rho))],$$

where:

- $M$  is any  $\Phi_m$ -split maximal torus of  $G$ .
- $D_m(\rho) = \varepsilon_{M, 1}(\rho) \deg \chi_{M, 1}(\rho)$ .
- For any  $\chi$ , we write  $[\Delta_{1/m}(\chi)]$  for the character of the associated Verma of the rational DAHA  $H_W^{\mathrm{rat}}(\frac{1}{m})$ .

$H_W^{\mathrm{rat}}(\frac{1}{m})$  is a highest-weight cover of  $H_W(\zeta_m)$ !

A very strange analogy emerges.

Below  $M$  is a  $\Phi_m$ -split maximal torus of  $G$ .

$\mathbf{GF}$

$\mathbf{G}$

$$\mathcal{Y}_e \times_{\mathbf{G}}^{\mathbf{L}} \mathcal{Y}_w$$

$$\mathcal{U}_e \times_{\mathcal{U}}^{\mathbf{L}} \mathcal{U}_w$$

$$(q, q)$$

$$(\zeta_m, 1)$$

$$H_W(q), H_{W_{G,M,1}}(q) \quad H_W^{\text{rat}}(\frac{1}{m}), H_{W_{G,M,1}}(1)$$

Thank you for listening.

Where else do we expect the formula on the  $\mathbf{G}$  side?

- Work of Oblomkov–Yun, Losev–Boixeda–Alvarez, *et al.* on *affine Springer fibers*.

- Work of Lusztig and Abreu–Nigro on analogues of  $\mathcal{U}_w$  replacing  $\mathcal{U}$  with a *regular semisimple* class of  $G$ .
