

Review recall F_X = free group on X

given a group G :

- $S \subseteq G$ is a generating set
iff no smaller subgroup of G contains S
iff the homomorphism F_S to G is surjective

in this case:

- $R \subseteq F_S$ is a set of relations wrt S
iff $\ker(F_S \rightarrow G)$ is the smallest kernel, i.e.,
normal subgp of F_S , containing R

then we can speak of a presentation of G
by generators and relations: $G = \langle S \mid R \rangle$
if $R = \emptyset$, then $G = F_S$ and we write $G = \langle S \rangle$

Rem any G has an “obvious” gen’ing set S :
[pause: what is it?]
take $S = G$ itself
[usually we prefer to study smaller S]

Ex take $G = \mathbb{Z}$
what is a one-elt gen’ing set? [pause]
 $S = \{1\}$ works [but also another:]
 $S = \{-1\}$ also works

what is a two-elt gen’ing set without ± 1 ? [pause]
[e.g.] $S = \{2, 3\}$

Ex last time, saw that if $G = \{e, s\}$
then $G = \langle s \mid s^2 \rangle$
[abusing notation: s should be $\{s\}$, etc.]

Ex let $G = \mathbb{Z}^2$ [under coordinate-wise +]
what is a generating set? [pause]
 $S = \{(1, 0), (0, 1)\}$ works

write $a = (1, 0)$ and $b = (0, 1)$

what is $\ker(F_S \text{ to } \mathbb{Z}^2)$? [pause]

elts of F_S are words in a, b, a^{-1}, b^{-1}

if such a word contains

M a 's,

N b 's,

M' a^{-1} 's,

N' b^{-1} 's

then it is mapped to $(M - M', N - N')$ in \mathbb{Z}^2 , so

$\ker(F_S \text{ to } \mathbb{Z}^2) = \{\text{words where}$
the net exponent of a &
the net exponent of b are
both zero}

e.g., for any w, v in F_S , it contains
the commutator $[w, v] := wvw^{-1}v^{-1}$
[here w^{-1} means the group inverse to w]

Fact ([follows from] Munkres 69.3–69.4)

- $\{[w, v] \mid w, v \text{ in } F_S\}$ is a generating set for $\ker(F_S \text{ to } \mathbb{Z}^2)$
- the kernel is the smallest normal subgp containing $[a, b]$

[defer proof for now]

altogether, get the presentation

$$Z^2 = \langle a = (1, 0), b = (0, 1) \mid aba^{-1}b^{-1} \rangle$$

Free Products [goal: Seifert–van Kampen:]
given groups
 $G_1 = \langle S_1 \mid R_1 \rangle,$
 $G_2 = \langle S_2 \mid R_2 \rangle:$

Df 1 the free product of G_1 and G_2 is
 $G_1 * G_2 = \langle S_1 \cup S_2 \mid R_1 \cup R_2 \rangle$

Problem a priori, $G_1 * G_2$ could depend
on how we present G_1 and G_2
[to solve this issue, new defn:]

Df 2 a free product of G_1, G_2 is a group G
with maps $i_1 : G_1 \rightarrow G, i_2 : G_2 \rightarrow G$
s.t., for any group K , we have a bijection

$\{\text{pairs of hom's } \varphi_1 : G_1 \rightarrow K, \varphi_2 : G_2 \rightarrow K\}$
 $=$
 $\{\text{hom's } \Phi : G \rightarrow K\}$

given explicitly by $\varphi_1 = \Phi \circ i_1$ and $\varphi_2 = \Phi \circ i_2$

Thm the free product in definition #2
is unique up to iso [in fact, “unique iso”]

Pf suppose $(G, i_1, i_2), (G', i'_1, i'_2)$
both work

taking $\varphi_k = i'_k$ above gives a hom $\Phi : G$ to G'
s.t. $i'_k = \Phi \circ i_k$

taking $\varphi_k = i_k$ above gives a hom $\Phi' : G'$ to G
s.t. $i_k = \Phi' \circ i'_k$

substituting, $i_k = \Phi' \circ \Phi \circ i_k$

so under the defining bijection for G ,

id_G and $\Phi' \circ \Phi$ both correspond to (i_1, i_2)

[pause: what next?] so $\text{id}_G = \Phi' \circ \Phi$

similarly, $\text{id}_{\{G'\}} = \Phi \circ \Phi'$

so Φ and Φ' are each other's two-sided inverses \square

[thm + proof illustrate “category-theoretic” ideas]

Lem $G_1 * G_2$ in defn #1 satisfies defn #2

Pf left as exercise

Ex the free group F_2 is isomorphic to $Z * Z$

more generally, $*$ is associative:

F_n is isomorphic to $Z * Z * \dots * Z$ with n copies

Ex let $G = \{e, s\}$, the two-elt group
how to write down elts of $G * G$? [pause]

need to distinguish two copies of s : say, “ s ” and “ t ”

$G * G = \{e, s, t, st, ts, sts, tst, \dots\}$

(Munkres §70) [but slightly changed notation]

Thm (Seifert–van Kampen) take open inclusions

$$j_1 : U_1 \text{ to } X,$$

$$j_2 : U_2 \text{ to } X$$

s.t. $X = U_1 \cup U_2$,

U_1 and U_2 are path connected,

$U := U_1 \cap U_2$ is path-connected

let $i_1 : U \text{ to } U_1$ and $i_2 : U \text{ to } U_2$ be inclusion
then for any x in U :

1) the homomorphism

$$\pi_1(U_1, x) * \pi_1(U_2, x) \text{ to } \pi_1(X, x)$$

arising from $(j_{1,*}, j_{2,*})$ via the defn

of free product is surjective

2) the kernel of the homomorphism is
the smallest normal subgp of the domain
containing the elts of the form

$$i_{1,*}([Y])^{-1} i_{2,*}([Y])$$

as we run over elts $[Y]$ in $\pi_1(U, x)$

[above, $i_{k,*}([Y])$ in $\pi_1(U_k, x)$, but then
we implicitly embed it into the free product]

Cor $\pi_1(X, x)$ is generated by the union of
 $\pi_1(U_1, x)$ and $\pi_1(U_2, x)$

Cor if there are open $U_1, U_2 \text{ sub } X$ s.t.
 U_1, U_2 are simply-connected,
 $X = U_1 \cup U_2$,
 $U_1 \cap U_2$ is path-connected,
then X is simply-connected

[we stated the latter corollary in a previous class]

Ex take a figure-eight:

[draw]

take open U_1, U_2 s.t.

they deformation retract onto the two loops

$U_1 \cap U_2$ def. retracts onto the middle pt

[draw]

then $\pi_1(U_1, x) = \pi_1(U_2, x) = \pi_1(S^1) = \mathbb{Z}$

but $\pi_1(U_1 \cap U_2, x)$ is trivial

so $\pi_1(\text{figure-eight}, x) = \mathbb{Z} * \mathbb{Z} = F_2$
