

(Munkres §25) recall that for any  $X$ :

the connected components of  $X$  are  
the equiv. classes where  $x \sim y$  iff  
there is a conn. subsp. containing  $x$  and  $y$

the path components of  $X$  are  
the equiv. classes where  $x \leftrightarrow y$  iff  
there is a path between  $x$  and  $y$  in  $X$

Lem the conn., resp. path components  
are the maximal nonempty  
conn., resp. path-conn. subspaces

[e.g., if  $A$  sub  $X$  conn, then  $A$  sub a conn. comp]

Pf by the def of an equiv. relation...

Q are conn. components open? closed?

Ex we say  $X$  is totally disconnected iff  
all nonempty conn. subspaces of  $X$   
are singletons

PS5, #1 says  $Q$  is totally disconnected in  $R$   
singletons in  $Q$  are closed, but not open

Thm if  $A$  sub  $X$  is conn, then  $Cl_X(A)$  is too  
  
more generally:  
any  $B$  s.t.  $A$  sub  $B$  sub  $Cl_X(A)$  is too

Cor conn. components of  $X$  are closed  
[by maximality]

Pf of Thm suppose  $U, V$  is a separation of  $B$

by Feb 5 lecture (also M. Lem. 23.2), know:  
since  $A$  is connected, either  $A \subset U$  or  $A \subset V$

then  $\text{Cl}_B(A) \subset \text{Cl}_B(U) = U$

but by Feb 3 lecture (also M. Thm. 17.4),

$\text{Cl}_B(A) = \text{Cl}_X(A) \cap B (= B \text{ here})$

so  $B \subset U$

contradicts  $V$  being nonempty  $\square$

Cor if  $X$  has finitely many conn. components  
then they are also open [thus clopen]

Q are path components open?  
closed?

Ex in the topologist's sine curve  
 $\check{S} = S \cup A$ ,  
where  $S = \{(x, \sin(1/x)) \mid x \in (0, 1]\}$   
 $A = \{(0, y) \mid y \in [-1, 1]\}$

we can check that  $S, A$  are the path components  
 $S$  is open but not closed  
 $A$  is closed but not open

Rem since path-connected implies connected

each path component of  $X$  is contained in  
some conn. component of  $X$

Q when can we ensure  
 $\{\text{conn. components of } X\}$   
 $=$   
 $\{\text{path components of } X\}$ ?

[helps to weaken our notions of conn., path-conn.]

Df  $X$  is locally connected at  $x$  iff,  
for all open  $U$  containing  $x$ ,  
there is a conn. open  $V$  s.t.  $x \in V \subset U$

similar def for locally path-connected,  
replacing conn.  $V$  with path-conn.  $V$

Ex  $[0, 1) \cup (1, 2]$  is loc. conn but not conn  
 $\mathbb{Q}$  is not locally connected

Thm if  $X$  is locally path-connected  
then its conn. comp's are path comp's

Lem if  $X$  is locally path-connected  
then for any open  $U \subset X$ ,  
path comp.  $P$  of  $U$ ,  
 $P$  is also open in  $X$

[similar lem for locally connected,  
replacing path comp.  $P$  with conn. comp.]

Pf pick  $x \in P$   
since  $X$  is locally path-connected,  
have path-conn. open  $V \subset U$  s.t.  
 $x \in V \subset U$   
by maximality of  $P$ , have  $V \subset P$

Pf of Thm      pick a conn. component  $C$  of  $X$

$C \neq \emptyset$  bc it's an equiv. class

so pick  $x$  in  $C$

let  $P$  be the path component containing  $x$

then  $P \subset C$ ; we want  $P = C$

any path component of  $X$  intersecting  $C$

is conn., hence contained in  $C$  [by max'ity]

let  $Q$  be the union of these except for  $P$

then  $C = P \cup Q$

claim that if  $Q \neq \emptyset$ , then a contradiction: [why?]

by lemma, each path comp. of  $X$  is open in  $X$

hence  $P, Q$  are open in  $X$ , hence in  $C$

hence  $P, Q$  would form a separation of  $C$   $\square$

(Munkres §26)       $X$  arbitrary top space

in analysis, two notions of compactness:

“sequential” compactness

“finite-cover” compactness

in topology, the latter is the standard notion

Df

an open cover of  $X$  is

a collection of open sets  $\{U_i\}_i$  in  $X$  s.t.

$X = \bigcup_i U_i$

[similar to a subbasis, but need not generate the topology]

a subcover of  $\{U_i\}_i$  is

a subcollection that remains a cover

we say that  $X$  is compact iff  
every cover of  $X$  admits a finite subcover

Ex       $\mathbb{R}$  not compact:  
take  $U_n = (n - 1, n + 1)$  for  $n \in \mathbb{Z}$

Ex       $\{1/n \mid n = 1, 2, 3, \dots\}$  not compact:  
[what cover?]  
take singletons  $\{1/n\}$  for  $n = 1, 2, 3, \dots$

Ex       $K = \{0\} \cup \{1/n \mid n \in \mathbb{N}\}$  is compact:  
  
any cover must include  $U$  s.t.  $0 \in U$   
then  $K - U$  is a finite set

Ex (Heine–Borel)     $[0, 1]$  is compact

[plays well with subspaces:]

Lem      TFAE for  $Y \subseteq X$ :

- 1)  $Y$  is compact as a subspace of  $X$
- 2) for any collection of opens  $\{U_i\}_i$  s.t.  
 $Y \subseteq \bigcup_i U_i$ ,  
there is a finite subcollection  $\{U_j\}_{j \in J}$  s.t.  
 $Y \subseteq \bigcup_{j \in J} U_j$

Pf      boring

Thm      closed subspaces of compact spaces  
are compact

thus Heine–Borel implies compactness of  $K$

Pf      let  $X$  be compact and  $Y$  closed

given collection of opens  $\{U_i\}_i$  in  $X$  s.t.

$Y \subset \bigcup_i U_i$

consider  $\{X - Y\} \cup \{U_i\}_i$

this is an open cover of  $X$ , since  $X - Y$  is open

so it has a finite subcover

even if we remove  $X - Y$  from this subcover,

it remains finite and its union contains  $Y$

[tell the Sorensen story?]
