The Gen and Cogen Formulas for Torus Knot Homology

1

(results joint with Oscar Kivinen)

triply-graded Khovanov–Rozansky homology:

$$\text{HHH} : \{\text{links}\}/\text{isotopy} \to \text{Vect}_{3\text{-gr}}$$

KhR polynomial: $\mathbf{P}_L(a, q, t) = \sum_{i,j,k} a^i q^j t^k \, \text{HHH}^{i,j,k}(L)$

2

(Elias–Hogancamp–Mellit)   computed $\mathbf{P}_{m,n} := \mathbf{P}_{\text{torus}(m,n)}$
for all $m, n > 0$

$$\text{torus}(m,n) = \widehat{\beta_n^m}, \quad \text{where } \beta_n = \sigma_1 \sigma_2 \cdots \sigma_{n-1} \in \text{Br}_n.$$

<u>Ex</u> $\mathbf{P}_{2,1} = \mathbf{P}_{\text{unknot}} = 1$ <u>Ex</u> $\mathbf{P}_{2,2} = 1 + \frac{qt}{1-q} + \frac{at}{1-q}$

<u>Ex</u> $\mathbf{P}_{2,3} = 1 + qt + at$

3

<u>Thm</u> $\displaystyle\sum_{\Delta \in D_{m,n}} q^{g_\Delta} t^{h_\Delta} f_\Delta^{\text{Gen}} \overset{\text{KT}}{=} \mathbf{P}_{m,n} \overset{\text{GMV}}{=} \sum_{\Delta \in D_{m,n}} q^{g_\Delta} t^{h_\Delta} f_\Delta^{\text{Cogen}}$

where the LHS requires m, n coprime

<u>Ex</u> $\mathbf{P}_{4,3}$ has 11 terms:

$q^{g_\Delta} t^{h_\Delta}$	Gen$^+$		Cogen	
$q^3 t^3$	$\emptyset$	1	$\{5\}$	$1 + aq^{-1}$
$q^2 t^2$	$\{5\}$	$1 + at$	$\{1,2\}$	$(1 + aq^{-1})(1 + aq^{-1}t)$
qt^2	$\{1\}$	$1 + at$	$\{2\}$	$1 + aq^{-1}$
qt	$\{2\}$	$1 + at$	$\{1\}$	$1 + aq^{-1}$
1	$\{1,2\}$	$(1 + at)(1 + at^2)$	$\emptyset$	1

4

$\mathbf{N}_0 = \{0, 1, 2, \ldots\}$

$$D_{m,n} = \{\Delta \subseteq \mathbf{N}_0 \mid \Delta + m, \Delta + n \subseteq \Delta \text{ and } 0 \in \Delta\}.$$

$g_\Delta = |\mathbf{N}_0 - \Delta|$

$h_\Delta = \sum_{k \in \text{Gen}_n(\Delta)} |\{k < j < k+n \mid j \notin \Delta\}|$, where

$$\text{Gen}_n(\Delta) = \{k \in \Delta \mid k - n \notin \Delta\}.$$

5

$\text{Gen}(\Delta) = \{k \in \Delta \mid k - m, k - n \notin \Delta\}$

$\text{Gen}^+(\Delta) = \text{Gen}(\Delta) - \{0\}$

$\text{Cogen}(\Delta) = \{k \in \mathbf{N}_0 - \Delta \mid k + m, k + n \in \Delta\}$

$$f_\Delta^{\text{Gen}} = \prod_{k \in \text{Gen}^+} (1 + at^{|\{j \in \text{Gen}_n \mid k-m < j < k\}|}),$$

$$f_\Delta^{\text{Cogen}} = \prod_{k \in \text{Cogen}} (1 + aq^{-1}t^{|\{j \in \text{Gen}_n \mid k+n < j < k+n+m\}|})$$

6

<u>Ex</u>   take $\Delta = \{0, 3, 4, 5, 6, \ldots\} = \mathbf{N}_0 - \{1, 2\}$ $\qquad \in D_{4,3}$

$\text{Gen}_3(\Delta) = \{0, 4, 5\}, \quad \text{Gen}^+(\Delta) = \{5\}, \quad \text{Cogen}(\Delta) = \{1, 2\},$

$$f_\Delta^{\text{Gen}} = 1 + at^{|\{j \in \text{Gen}_3 \mid 5-4 < j < 5\}|}$$

$$= 1 + at$$

$$f_\Delta^{\text{Cogen}} = (1 + aq^{-1}t^{|\{j \in \text{Gen}_3 \mid 1+3 < j < 1+7\}|})$$

$$\cdot (1 + aq^{-1}t^{|\{j \in \text{Gen}_3 \mid 2+3 < j < 2+7\}|})$$

$$= (1 + aq^{-1}t)(1 + aq^{-1})$$

7

Gen formula from Mellit, <u>G&T</u> (2022)

Cogen formula from Hogancamp–Mellit, arXiv:1909.00418,
   via Gorsky–Mazin–Vazirani (2020)

Both rely on recursions from Elias–Hogancamp (2019)

In turn starts from Khovanov (2008):

braid β $\quad\rightsquigarrow\quad$ bimodule complex F_β $\quad\rightsquigarrow\quad$ $\mathrm{HHH}(\hat{\beta})$

8

Mellit's recursion decomposes β_n^m into a sum indexed by
m/n Dyck paths:

bijection $D_{m,n} \xrightarrow{\sim} \{m/n \text{ Dyck paths } \pi\}$

role of Dyck paths predicted by Gorsky–Neguţ (2016)

start with diagonal and "sweep up" applying local rules
from Mellit, <u>Duke</u> (2021)

9

$$\nu_*(\pi) = \{\text{bottom right corners of squares} \searrow \pi\}$$
$$\nu^*(\pi) = \{\text{top left corners of squares} \nwarrow \pi\}$$

<u>Lem</u>   if $\Delta \mapsto \pi$, then:

(1) $\{j \in \mathrm{Gen}_n(\Delta) \mid k - m < j < k\} \xrightarrow{\sim} \nu_*(\pi)$

(2) $f_\Delta^{\mathrm{Gen}} = \prod_{p \in \nu_*(\pi)} \left(1 + at^{|\kappa_\pi(p)|}\right) = \frac{1}{1+a} \prod_{p \in \nu^*(\pi)} \left(1 + at^{|\kappa_\pi(p)|}\right)$

where $\kappa_\pi(p) = \{\text{horizontal steps of } \pi \text{ meeting } l_{m/n}(p)\}$

10

we used the Gen formula to show:

<u>Thm</u>   for fixed $n > 0$,

$$\frac{1}{1-q} \lim_{\substack{m \to \infty \\ m,\, n \text{ coprime}}} \mathbf{P}_{m,n}(a,q,t) = \prod_{1 \le j \le n} \frac{1 + at^{j-1}}{1 - qt^{j-1}}$$

$\frac{1}{1-q} \mathbf{P}_{m,n}(a,q,t)$ is determined by its expansion up to q-degree $\frac{(m-1)(n-1)}{2}$, by palindromicity of $\mathbf{P}_{m,n}$

11

<u>Cor</u>   formula for $\mathbf{P}_{m,n}$ when $n \le 3$ and m, n coprime

<u>Pf</u> $\frac{1}{1-q} \mathbf{P}_{m,n}$ matches $\frac{1}{1-q} \mathbf{P}_{\infty,n}$ up to q-degree m

<u>Cor</u>   the ORS conjecture for $y^n = x^m$:

$$\frac{\mathbf{P}_{m,n}(a,q,qt^2)}{1-q} = \sum_{k,\ell} a^k q^\ell t^{k^2-k} \chi(t, \underbrace{\mathrm{Hilb}^\ell_{k\text{-nest}}(y^n = x^m)}_{\subseteq \, \mathrm{Hilb}^\ell \times \mathrm{Hilb}^{\ell+k}}))$$

<u>Pf</u>   ORS established a matching formula on the Hilb side
